Marc Dupuis

Un stage qui portera ses fruits

par **Christine Bernard**

Marc Dupuis a récemment complété son baccalauréat en génie chimique à l'Université Laval. Il prépare sa maîtrise pour l'automne. Cet été, il a consacré son travail à la recherche pour le compte du Centre de recherche et de développement Arvida.

Pendant quatre mois, il a simulé, avec des modèles mathématiques, la circulation de l'air dans les salles de cuves. Ces modèles permettent d'aboutir plus rapidement à des solutions

susceptibles d'améliorer les conditions de travail des employés.

Relations humaines

Il en est à sa première expérience à Arvida. C'est également la première fois qu'il travaille spécifiquement dans son domaine. Mais il voulait absolument voir ce qu'est le travail en usine. Il considère que l'école ne peut tout lui apprendre. Les relations avec les employés sont très importantes, et à ce titre sont essentielles à la formation. "On n'apprend

que sur le métier", précisait-il.

Expérience à transmettre

"Je voulais absolument voir ce qu'est le travail en industrie." Marc Dupuis souligne également que les cours sont parfois très théoriques et, en cela, demeurent assez loin de la réalité. La théorie et la pratique font un complément, et c'est cela qu'il essaiera de transmettre aux plus jeunes étudiants, quand il retournera à Québec.

1980-84, 2D potroom ventilation model

1980-84, 2D potroom ventilation model

Experimental results

Best model results

The best results of my Ph.D. work: the 2D finite difference vorticity-stream function formulated model could not reproduce well the observed air flow regardless of the turbulence model used.

1984, 3D thermo-electric half anode model

```
ANSYS  
10/31/84

YU=1  
ZU=1  
DIST=973  
XF=328  
YF=122  
ZF=868  
ANGL=90  
HIDDEN
```

That model was developed on ANSYS 4.1 installed on a shaded VAX 780 platform.

That very first 3D half anode model of around 4000 Solid 69 thermo-electric elements took 2 weeks elapse time to compute on the VAX.

1984, Instrumented Anode Setup

1986, 3D thermo-electric cathode side slice and cathode corner model

The next step was the development of a 3D cathode side slice thermo-electric model that included the calculation of the thickness of the solid electrolyte phase on the cell side wall .

Despite the very serious limitations on the size of the mesh, a full cathode corner was built next .

Design of 2 high amperage cell cathodes

1987: Apex 4

1989: A310

Comparison of the predicted versus measured behavior was within 5% in both cases, demonstrating the value of the numerical tools developed.

1988, 3D cathode potshell plastic deformation mechanical model

The new model type addresses a different aspect of the physic of an aluminum reduction cell, namely the mechanical deformation of the cathode steel potshell under its thermal load and more importantly its internal pressure load .

1989, 3D cathode potshell plastic deformation and lining swelling mechanical model

First “Half Empty shell” potshell model developed in 1989 and presented at a CRAY Supercomputing Symposium in 1990

1992, 3D thermo-electric quarter cathode model

With the upgrade of the P-IRIS to 4D/35 processor, and the option to run on a CRAY XMP supercomputer, the severe limitations on the CPU usage were finally partially lifted.

This opened the door to the possibility to develop a full 3D thermo-electric quarter cathode model.

1992, 3D thermo-electric “pseudo” full cell and external busbars model

As a first step toward the development of a first thermo-electro-magnetic model, a 3D thermo-electric “pseudo” full cell and external busbars model was developed.

That model was really at the limit of what could be built and solved on the available hardware at the time both in terms of RAM memory and disk space storage.

1992, 3D cathode potshell plastic deformation and lining swelling mechanical model

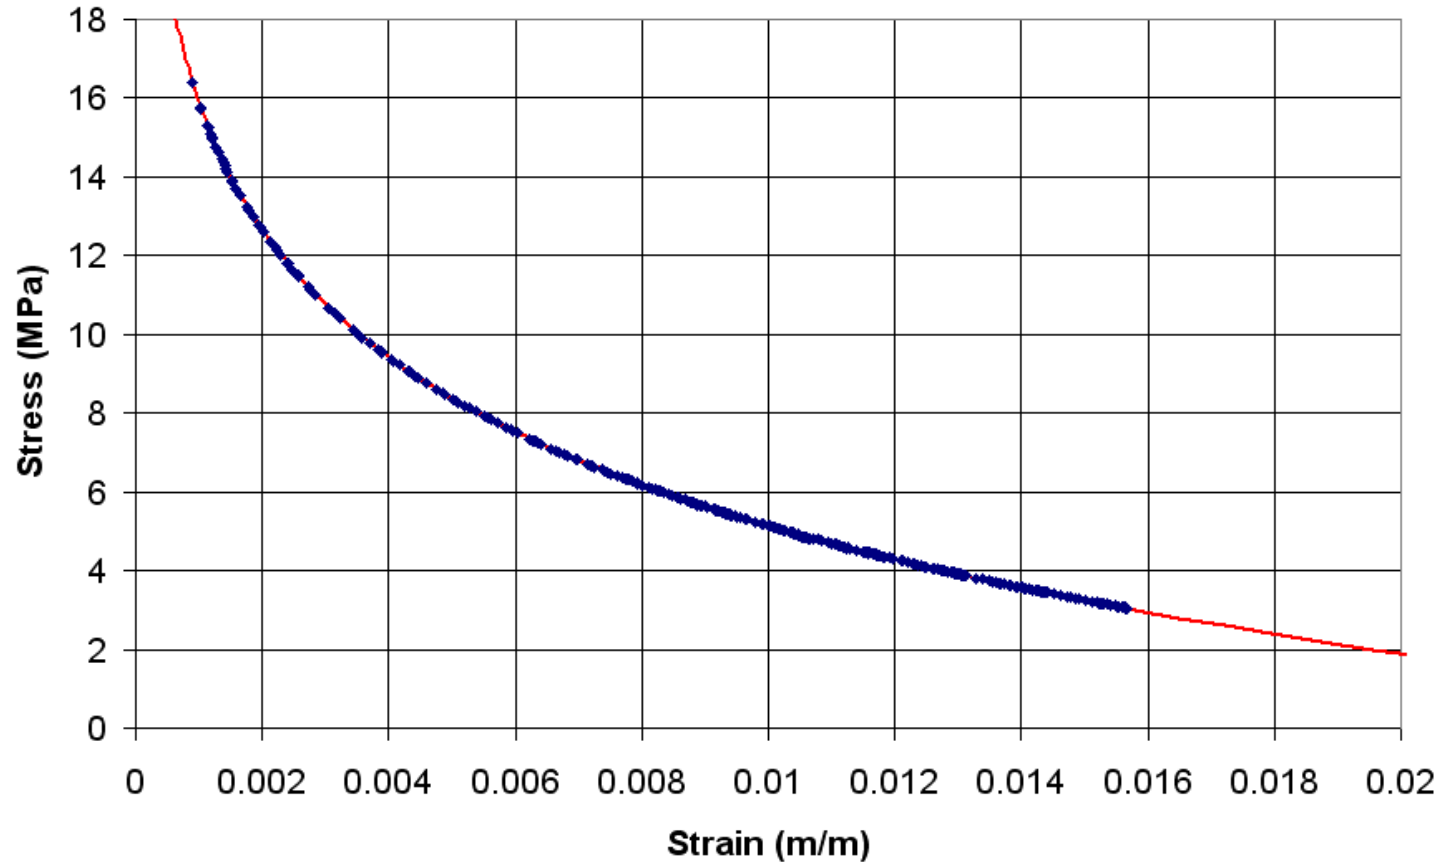

The empty quarter potshell mechanical model was extended to take into account the coupled mechanical response of the swelling lining and the restraining potshell structure.

That coupling was important to consider as a stiffer, more restraining potshell will face more internal pressure from the swelling lining material.

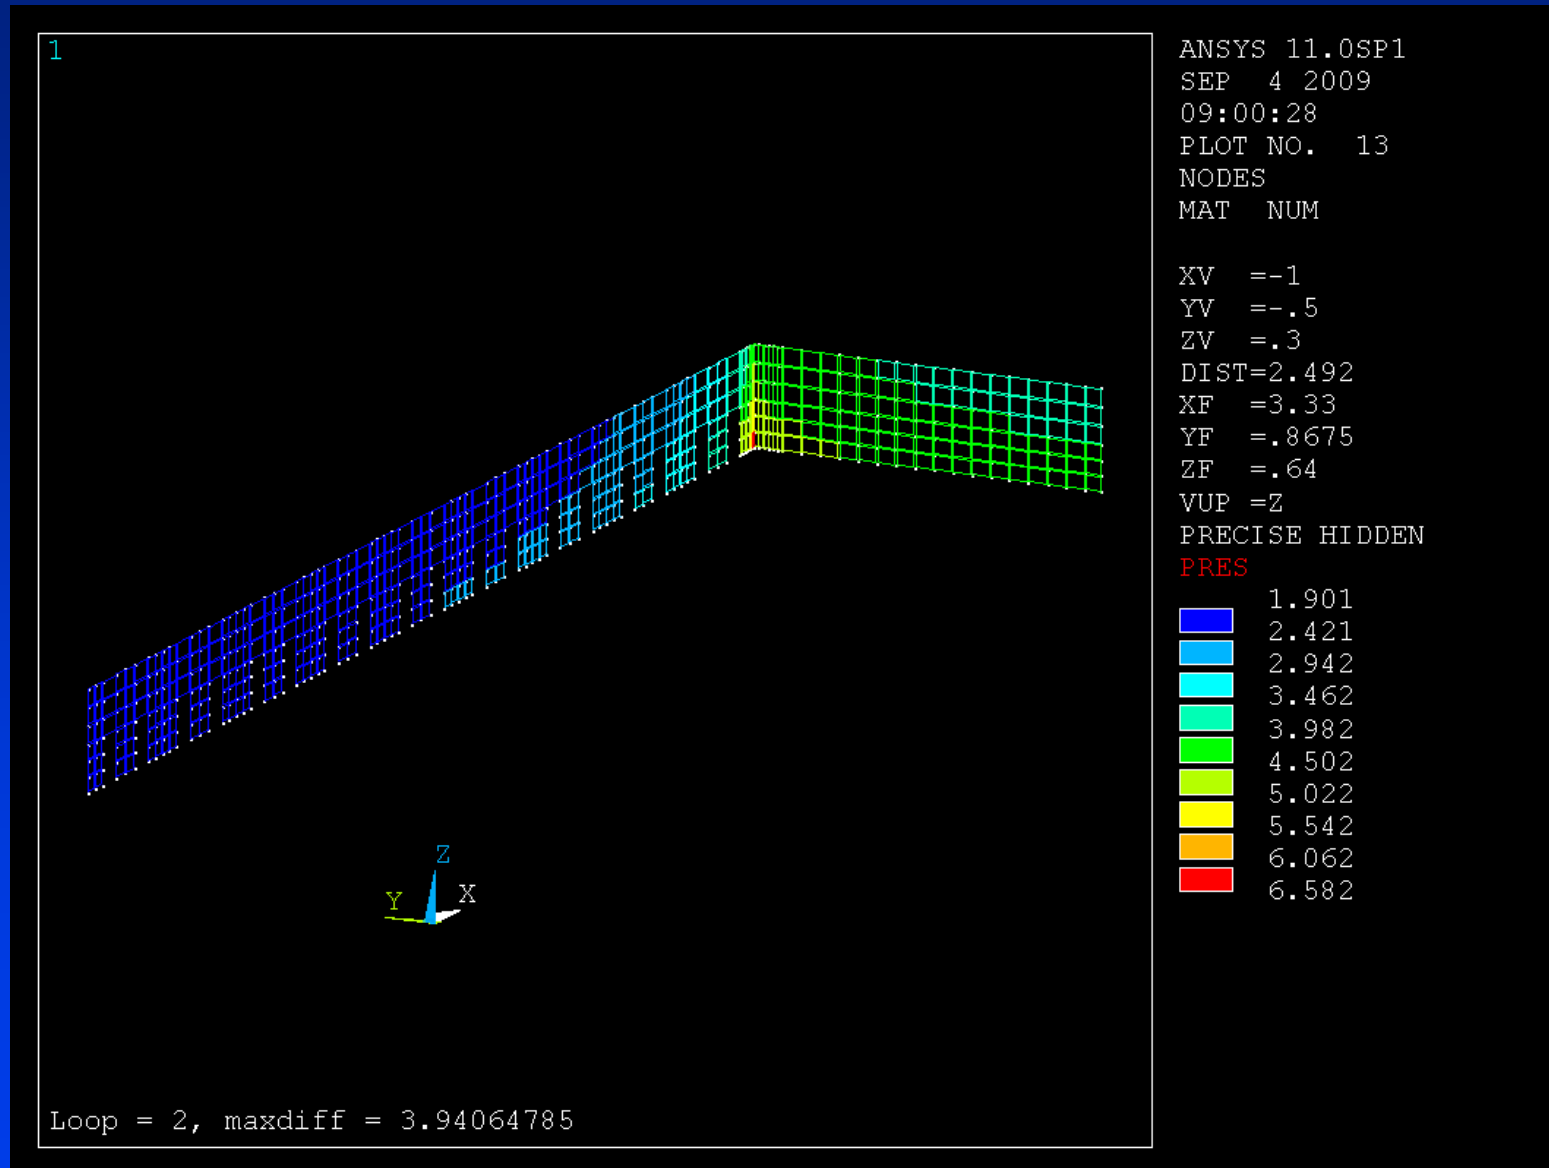

1992, 3D cathode potshell plastic deformation and lining swelling mechanical model

Individual element face strain-stress location on the Dering curve
Elastic mode

A numerical scheme external to the ANSYS solver must be setup, starting from an assumed initial internal load. The task of that external numerical scheme is to converge toward that cathode block equilibrium condition pressure loading for each element face of the carbon block/side lining interface.

1992, 3D cathode potshell plastic deformation and lining swelling mechanical model

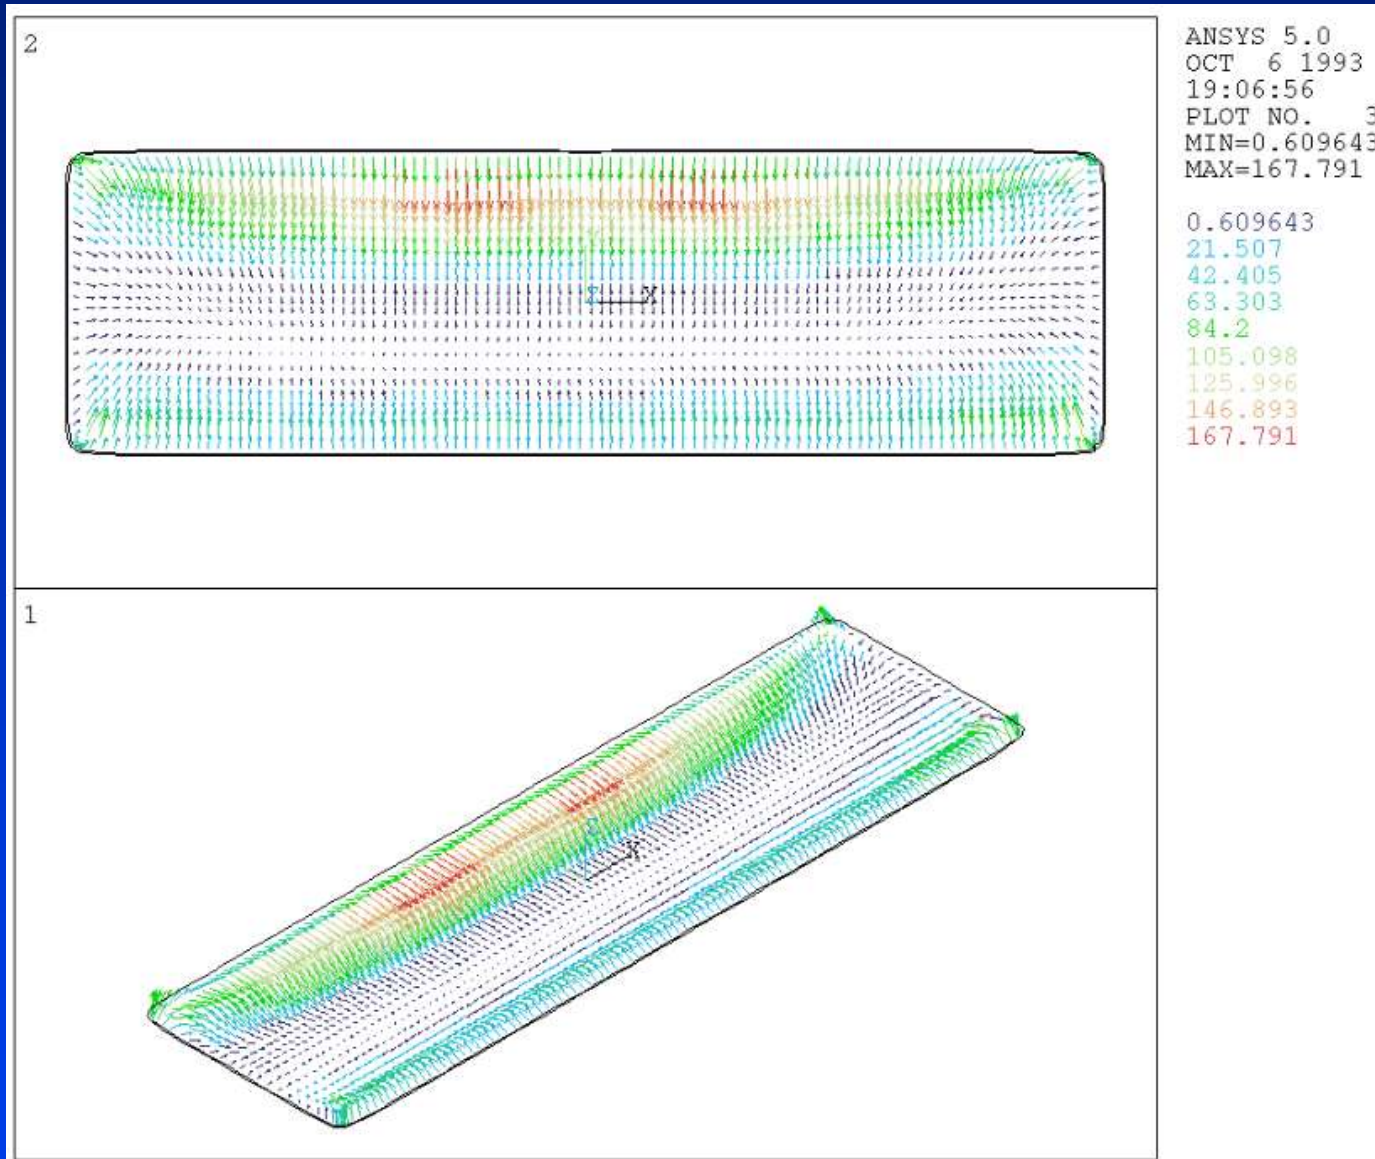

1993, 3D electro-magnetic full cell model

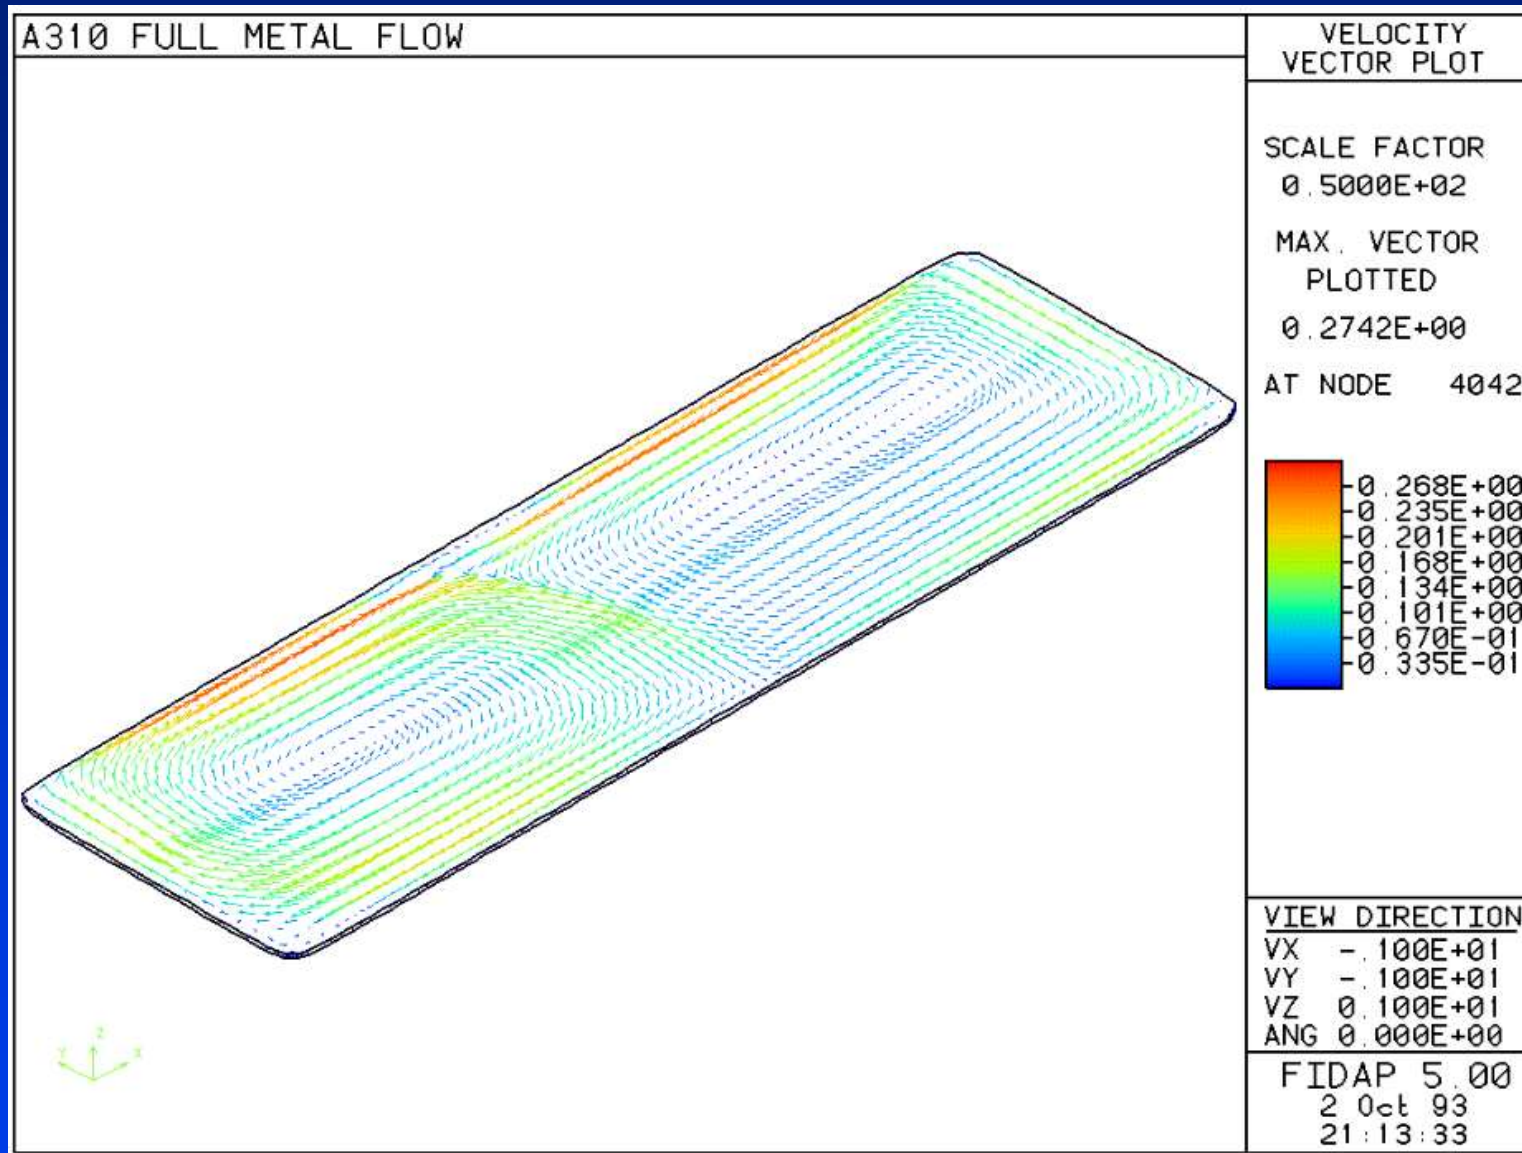

The development of a finite element based aluminum reduction cell magnetic model clearly represented a third front of model development.

Because of the presence of the ferro-magnetic shielding structure, the solution of the magnetic problem cannot be reduced to a simple Biot-Savard integration scheme.

1993, 3D electro-magnetic full cell model

1993, 3D electro-magnetic full cell model

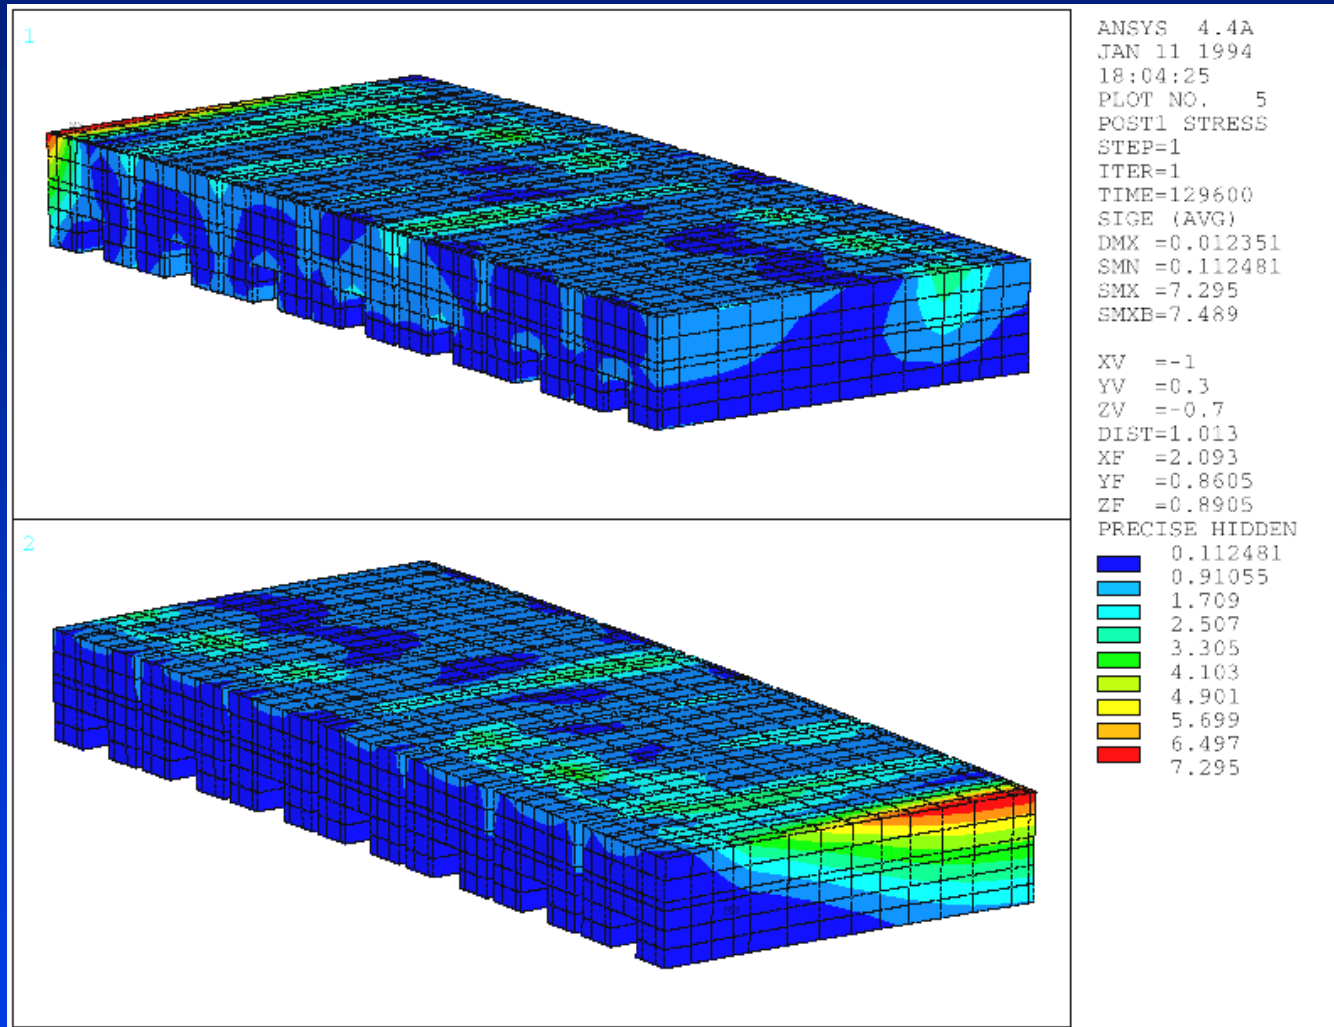

1993, 3D transient thermo-electric full quarter cell preheat model

The cathode quarter thermo-electric model was extended into a full quarter cell geometry in preheat configuration and ran in transient mode in order to analyze the cell preheat process .

The need was urgent, but due to its huge computing resources requirements, the model was not ready in time to be used to solve the plant problem at the time.

1993's Model Extension to Stress Analysis

Equivalent stress in the cathode panel at 36 hours – standard coke bed

1993, 2D CFDS-Flow3D potroom ventilation model

1993, 2D CFDS-Flow3D potroom ventilation model

2D “Reynolds flux” model results vs. physical model results

1998, 3D thermo-electric full cell slice model

As described previously, the 3D half anode model and the 3D cathode side slice model have been developed in sequence, and each separately required a fair amount of computer resources.

Merging them together was clearly not an option at the time, yet it would have been a natural thing to do. Many years later, the hardware limitation no longer existed so they were finally merged.

1998, 2D+ thermo-electric full cell slice model

2D+ version of the same full cell slice model was developed. Solving a truly three dimensional cell slice geometry using a 2D model may sound like a step in the wrong direction, but depending on the objective of the simulation, sometimes it is not so.

The 2D+ model uses beam elements to represent geometric features lying in the third dimension (the + in the 2D+ model).

1999, 2D+ transient thermo-electric full cell slice model

An interesting feature of that model is the extensive APDL coding that computes other aspects of the process related to the different mass balances like the alumina dissolution, the metal production etc.

As that type of model has to compute the dynamic evolution of the ledge thickness, there is a lot more involved than simply activating the ANSYS transient mode option.

2000, 3D thermo-electric cathode slice erosion model

Cathode erosion rate is proportional to the cathode surface current density and that the initial surface current density is not uniform, the erosion profile will not be uniform.

Furthermore, that initial erosion profile will promote further local concentration of the surface current density that in turn will promote a further intensification of the non-uniformity of the erosion rate.

Future developments

Currently, we can fit Hall-Héroult mathematical models into three broad categories:

- Stress models which are generally associated with cell shell deformation and cathode heaving issues.
- Magneto-hydro-dynamic (MHD) models which are generally associated with the problem of cell stability.
- Thermal-electric models which are generally associated with the problem of cell heat balance.

Cell
Design

Future developments

Yet, to be rigorous, a fusion of those three types of model into a fully coupled multi-physics finite element model is required because:

- MHD is affected by the ledge profile, mostly dictated by the cell heat balance design.
- local ledge profile is affected by the metal recirculation pattern mostly dictated by the busbars MHD design .
- shell deformation is strongly influenced by the shell thermal gradient controlled by the cell heat balance design.
- steel shell structural elements like cradles and stiffeners influence the MHD design through their magnetic shielding property.
- global shell deformation affects the local metal pad height, which in turn affects both the cell heat balance and cell stability

3D fully coupled thermo-electro-mechanico- magneto-hydro-dynamic full cell and external busbar model weakly coupled with a 3D potroom ventilation model
